CompVP Project Part 1

Group: Annika Heil

The 100 objects were selected from the OmniObject3D [1] dataset, which contains a huge amount of scanned 3D objects.

To normalize the objects to the unit scale and reduce their mesh size, two filter functions from the library PyMeshLab [2] were used.

Blender 3.6 [3] was chosen for the simulations of the cloth draping.

While trying different settings for the cloth draping, the most sufficiently realistic results were accomplished by using the collision object and cloth settings, that are written in the two tables on the right.

For especially pointed objects a slight problem occurred with those settings. The pointed top-most part would “stab” through the cloth and thereby would no longer be occluded. To fix this problem a slightly increased “Thickness Outer” was used for such objects. The highest used value for this parameter was 0.015.
